# L11: Unique Factorization Domains

#### Definition 11.1: Irreducible/Reducible, Prime, Associate Elements

Let R be an integral domain

(i) Suppose  $r \in R \setminus \{0\}, r \notin R^{\times}$ .

We say r is **irreducible** if whenever  $r = a \cdot b$ , either  $a \in R^{\times}$  or  $b \in R^{\times}$ . We say r is **reducible** if it is not irreducible.

(ii) Suppose  $r \in R \setminus \{0\}, r \notin R^{\times}$ 

We say r is **prime** if (r) is a prime ideal.

In other words, if  $r \mid a \cdot b$ , then either  $r \mid a$  or  $r \mid b$ .

(iii) We say  $a, b \in R$  are associates if there exists  $u \in R^{\times}$  such that  $a = u \cdot b$ .

#### Proposition 11.2: Prime elements in integral domain are irreducible

Any prime element in an integral domain is irreducible.

**Proof.** Suppose  $p = a \cdot b \in R$  and (p) is a prime ideal.

Then  $p \in (p)$  implies  $a \in (p)$  or  $b \in (p)$ . W.l.o.g let  $a \in (p)$ .

So  $\exists r \in R$  such that  $a = p \cdot r$  and hence

$$p = (p \cdot r) \cdot b = p \cdot (r \cdot b)$$

Since R is an integral domain then,  $1 = r \cdot b$ , so  $b \in R^{\times}$ .

Example 11.1. Irreducible but not prime.

Consider the ring

$$\mathbb{Z}[\sqrt{-5}] := \{a + b\sqrt{-5} \mid a, b \in \mathbb{Z}\}\$$

Then

- $N(a + b\sqrt{-5}) := a^2 + 5b^2$
- $N(x \cdot y) = N(x) \cdot N(y)$
- $N(x) = \pm 1$  if an only if  $x \in \mathbb{Z}[\sqrt{-5}]^{\times}$

Claim:  $2 + \sqrt{-5}$  is irreducible

**Proof.** Suppose

$$2 + \sqrt{-5} = (a + b\sqrt{-5}) \cdot (c + d\sqrt{-5})$$

Then

$$N(2+\sqrt{-5}) = 4+5=9 \implies N(a+b\sqrt{-5}) \mid 9 \implies N(a+b\sqrt{-5}) = \pm 1 \text{ or } \pm 3$$

**Observe** that if  $b \neq 0$ , then

$$N(a + b\sqrt{-5}) = a^2 + 5b^2 \ge 5$$

Therefore

$$b=0 \implies N(a+b\sqrt{-5})=N(a)=a^2 \implies N(a+b\sqrt{-5})=1 \implies a+b\sqrt{-5} \in \mathbb{Z}[\sqrt{-5}]^\times$$

Claim:  $2 + \sqrt{-5}$  is **not** prime.

**Proof.** We know

$$3^2 = 9 = (2 + \sqrt{-5}) \cdot (2 - \sqrt{-5}) \in (2 + \sqrt{-5})$$

However,  $3 \notin (2 + \sqrt{-5})$ .

If  $3 = (a + b\sqrt{-5}) \cdot (2 + \sqrt{-5})$ , then

$$9 = N(3) = N(a + b\sqrt{-5}) \cdot N(2 + \sqrt{-5}) = N(a + b\sqrt{-5}) \cdot 9 \implies N(a + b\sqrt{-5}) = 1$$

which immediately tells us b = 0 and  $a = \pm 1$ .

But  $3 \notin \pm (N(a+b\sqrt{-5}) \cdot N(2+\sqrt{-5}))$ 

#### Proposition 11.3: Element in PID is prime iff it is irreducible

In a PID an element is prime *iff* it is irreducible.

**Proof.** It suffices to show that irreducible  $\implies$  prime.

Suppose  $r \in R$  is irreducible and recall that maximal ideals are prime. Hence we will show that (r) is maximal.

Suppose  $(r) \subset (m) \subseteq R$ , then

$$r \in (m) \implies \exists s \in R, r = s \cdot m \implies r \text{ irreducible } \implies s = R^{\times} \text{ or } m \in R^{\times}$$

By assumption  $(m) \subsetneq R$  and this implies

$$m \notin R^{\times} \implies s \in R^{\times} \implies (r) = (m)$$

**Example 11.2.** In  $\mathbb{Z}$ , the irredcibles are the primes (and their negatives)

Observe that the factorization of any integer into primes is unique!

## Definition 11.4: Unique Factorization Domain

A unique factorization domain (UFD) is an integral domain R such that for all  $r \in r \setminus \{0\}, r \notin R^{\times}$ 

- (i)  $r = p_1 \cdot p_2 \cdot \ldots \cdot p_k$  for  $p_i$  irreducible.
- (ii) This decomposition is unique up to associates and reordering, i.e if

$$r = q_1 \cdot \ldots \cdot q_m, \quad q_j \text{ irreducible}$$

Then after reordering,  $q_i = u_i p_i, u_i \in R^{\times}$  and n = m.

**Example 11.3.** Fields are vacuously UFDs

Example 11.4.  $\mathbb{Z}$  are a UFD

Example 11.5.  $\mathbb{Z}[\sqrt{-5}]$  is not a UFD as

$$3^2 = (2 + \sqrt{-5}) \cdot (2 - \sqrt{-5})$$

and  $3, 2 \pm \sqrt{-5}$  are irreducibles.

#### Proposition 11.5: Element in UFD is prime iff it is irreducible

In a UFD, an element is prime *iff* it is irreducible.

**Proof.** It suffices to show once more that irreducible  $\implies$  prime.

Suppose  $r \in R$  is irreducible and  $a \cdot b \in (r)$  i.e there exists  $c \in R$  such that  $a \cdot b = r \cdot c$ By unique factorization

$$a = p_1 \cdot p_2 \cdot \dots p_n$$
,  $p_i$  irreducible, unique

$$b = q_1 \cdot q_2 \cdot \dots q_n$$
,  $q_i$  irreducible, unique

$$c = r_1 \cdot r_2 \cdot \dots r_l$$
,  $r_k$  irreducible, unique

Hence

$$p_1 \cdot p_2 \cdot \ldots \cdot p_n \cdot q_n \cdot \ldots \cdot q_m = r \cdot r_1 \cdot r_2 \cdot \ldots \cdot r_l$$

so by unique factorization, w.l.og

$$r = u \cdot p_1, \ u \in R^{\times} \implies r|a$$

### Proposition 11.6: Nonzero elements in UFD have GCD

Let  $a, b \in R \setminus \{0\}$  in a UFD. Then there is a greatest common divisor of a, b in R.

**Proof.** We write for  $u, v \in R^{\times}$  and  $p_i$ 's irreducible

$$a=u\boldsymbol{\cdot} p_1^{e_1}\boldsymbol{\cdot} p_2^{e_2}\boldsymbol{\cdot}\ldots\boldsymbol{\cdot} p_n^{e_n}b=v\boldsymbol{\cdot} p_1^{f_1}\boldsymbol{\cdot} p_2^{f_2}\boldsymbol{\cdot}\ldots\boldsymbol{\cdot} p_n^{f_n}$$

We allow some exponents to be 0  $(p_i^0 = 1)$  and we require  $p_i \neq p_j$  if  $i \neq j$  for example

$$\begin{pmatrix} 12 = 2^2 \cdot 3 \to 12 = 2^2 \cdot 3^1 \cdot 5^0 \\ 20 = 2^2 \cdot 5 \to 20 = 2^2 \cdot 3^0 \cdot 5^1 \end{pmatrix}$$

Claim:  $d = p_1^{\min\{e_1,d_1\}} \cdot p_2^{\min\{e_2,d_2\}} \cdot \dots \cdot p_n^{\min\{e_n,d_n\}}$  is the gcd(a,b).

**Proof.** Clearly  $d \mid a, d \mid b$ .

If  $c \mid a, c \mid b$ , then we want to see that  $c \mid d$ .

Unique factorization says for  $q_i$  irreducible,  $q_i \neq q_j$  and  $g_i > 0$ , we have

$$c = q_1^{g_1} \bullet \dots \bullet q_m^{g_m}$$

Since  $c \mid a, c \mid b$ , then after changing associates

$$\{q_1,\ldots,q_n\}\subset\{p_1,\ldots,p_n\},\ g_i\leq\min\{e_i,f_i\}\implies c\mid d$$

And so there exists a greatest common divisor of a, b in R.
